## 1 Language

### 1.1 Term and Pools

We inductively define *terms*, *tuples of terms*, and *pools*:

- all numerals, symbolic constants, and variables are terms,<sup>[1]</sup> [1] R: Define those things.
- $f(\mathbf{t})$  is a term, if  $f$  is a symbolic constant and  $\mathbf{t}$  is a pool,
- $t_1 \star t_2$  is a term, if  $\star$  is among the symbols  $+$ ,  $-$ ,  $\times$ ,  $/$  or  $..$  and  $t_1, t_2$  are terms,
- $\langle \mathbf{t} \rangle$  is a term, if  $\mathbf{t}$  is a pool,
- $t_1, \dots, t_n$  is a tuple of terms, if  $n \geq 0$  and  $t_i$  is a term,
- $\dot{t}_1; \dots; \dot{t}_n$  is a pool, if  $n \geq 1$  and each  $\dot{t}_i$  is a tuple of terms.<sup>[2]</sup> [2] R: Why not empty?

We inductively define a term to be *numeric* if

- it is a numeral, or
- it has form  $t \star u$  where  $t$  and  $u$  are constant and  $\star$  is among the symbols  $+$ ,  $-$ ,  $\times$  or  $/$ .

We define function *eval* to evaluate numeric terms to sets of numerals:

$$\begin{aligned} eval(c) &= \{c\} \\ eval(a + b) &= \{x + y \mid x \in eval(a), y \in eval(b)\} \\ eval(a - b) &= \{x - y \mid x \in eval(a), y \in eval(b)\} \\ eval(a * b) &= \{x * y \mid x \in eval(a), y \in eval(b)\} \\ eval(a/b) &= \{x/y \mid x \in eval(a), y \in eval(b), y \neq 0\} \end{aligned}$$

We say that a term  $c$  is *nonzero* if it is numeric and  $0 \notin eval(c)$ .

## 1.2 Atoms and Literals

An *atom* has form  $p(\mathbf{t})$  where  $p$  is a predicate symbol and  $\mathbf{t}$  is a pool.<sup>[3]</sup>

<sup>[3]</sup> R: Define predicate symbols.

A *comparison* has form  $t_1 \prec t_2$ , where  $t_1, t_2$  are terms and  $\prec$  is among the symbols  $\leq, \geq, <, >$  or  $\neq$ .

A *literal* is either an atom or a comparison optionally preceded by the *default negation* symbol  $\neg$ .

A *conditional literal* has form  $l : \dot{l}$ , where  $l$  is a literal and  $\dot{l}$  is a (possibly empty) tuple of literals.

## 1.3 Aggregates

An *aggregate* has the form

$$\alpha\{\dot{t}_1 : \dot{l}_1; \dots; \dot{t}_n : \dot{l}_n\} \prec s \quad (1)$$

where

- $n \geq 0$ ,
- $\alpha$  is an aggregate name,
- each  $\dot{t}_i$  is a tuple of terms,
- each  $\dot{l}_i$  is a tuple of literals,
- $\prec$  is among the symbols  $\leq, \geq, <, >, =$  or  $\neq$ , and
- $s$  is a term.

## 1.4 Rules

A *rule* has form

$$a_1 \vee \dots \vee a_m \leftarrow l_1 \wedge \dots \wedge l_n \quad (2)$$

where  $m, n \geq 0$ , each  $a_i$  is a literal and each  $l_i$  is a literal, conditional literal or aggregate.

A *choice rule* has form

$$\{a_1; \dots; a_m\} \leftarrow l_1 \wedge \dots \wedge l_n \quad (3)$$

where  $m, n \geq 0$ , each  $e_i$  is an atom and each  $l_i$  is a literal, conditional literal or aggregate.

We refer to the atoms  $a_i$  and literals  $l_i$  in rules of form (2) and (3) as *head atoms* and *body literals*, respectively.

## 2 Safety

In the following, we use function  $vars(e)$  to obtain all variables occurring in an expression  $e$ . We say that a variable  $X$  occurs *globally* in

- a literal  $l$  if  $X \in vars(l)$ ,
- a conditional literal  $l : \dot{l}$  if  $X \in vars(l) \setminus vars(\dot{l})$ ,
- an aggregate of form (1) if  $X \in s$ , and
- a rule of form (2) or (3) if it occurs globally in a head atom or body literal.

### 2.1 Terms

We inductively define function  $pt$  for terms, tuples of terms, and pools:

- for numerals  $n$  and symbolic constants  $f$ , we let  $pt(n) = pt(f) = \emptyset$ ,
- for variables  $X$ , we let  $pt(X) = \{X\}$ ,
- for term tuples  $\dot{t} = t_1, \dots, t_n$ , we let  $pt(\dot{t}) = pt(t_1) \cup \dots \cup pt(t_n)$ ,
- for pools  $\mathbf{t} = \dot{t}_1; \dots; \dot{t}_n$ , we let  $pt(\mathbf{t}) = pt(\dot{t}_1) \cap \dots \cap pt(\dot{t}_n)$ ,
- for a term of form  $f(\mathbf{t})$ , we let  $pt(f(\mathbf{t})) = pt(\mathbf{t})$ ,
- for a term of form  $t_1 \star t_2$ , we let

$$pt(t_1 \star t_2) = \begin{cases} pt(t_2) & t_1 \text{ is numeric and } \star \in \{+, -\}, \text{ or} \\ & t_1 \text{ is nonzero and } \star = \times, \\ pt(t_1) & t_2 \text{ is numeric and } \star \in \{+, -\}, \text{ or} \\ & t_2 \text{ is nonzero and } \star = \times, \\ \emptyset & \text{otherwise} \end{cases}$$

We define function  $dt$  for a term  $t$  as  $dt(t) = vars(t) \setminus pt(t)$ .

### 2.2 Atoms and Literals

#### 2.2.1 Atoms and Literals

For an literal of form *not*  $a$ , where  $a$  is an atom

$$dep(not\ a) = \{(\emptyset, vars(a))\}$$

For an atom of form  $p(\mathbf{t})$ , where  $\mathbf{t}$  is a pool

$$dep(p(\mathbf{t})) = \{(pt(\mathbf{t}), \emptyset), (\emptyset, dt(\mathbf{t}))\}$$

### 2.2.2 Comparison Literals

For an comparison literal of form  $a \prec b$ , where  $a$  and  $b$  are terms and  $\prec$  is among the symbols  $\leq, \geq, <, >, \neq$

$$dep(a \prec b) = \{(\emptyset, vars(a \prec b))\}$$

For an comparison literal of form  $a = b$ , where  $a$  and  $b$  are terms

$$dep(a = b) = \{(pt(a), vars(b)), (pt(b), vars(a)), (\emptyset, dt(a) \cup dt(b))\}$$

For an literal of form  $not\ a \prec b$ , where  $a$  and  $b$  are terms

$$\begin{aligned} dep(not\ a = b) &= dep(a \neq b) \\ dep(not\ a \neq b) &= dep(a = b) \\ dep(not\ a \leq b) &= dep(a > b) \\ dep(not\ a > b) &= dep(a \leq b) \\ dep(not\ a \geq b) &= dep(a < b) \\ dep(not\ a < b) &= dep(a \geq b) \end{aligned}$$

### 2.2.3 Conditional Literals

For a conditional literal of form  $\dot{t} : \dot{c}$ , where  $t$  is a tuple of terms and  $c$  is a tuple of comparison literals and atoms, where  $G$  is the set of variables occuring globally in it.

$$dep(\dot{t} : \dot{c}) = \{(\emptyset, G \cup vars(s))\}$$

For an conditional literal of form  $\dot{t} : \dot{c}$ , where  $t$  is a tuple of terms and  $c$  is a tuple of comparison literals and atoms in a local context

$$dep_l(\dot{t} : \dot{c}) = \{(\emptyset, vars(\dot{t}))\} \cup \bigcup_{e \in \dot{c}} dep(e)$$

## 2.3 Aggregates

For a aggregate  $a$  occuring in a rule, where  $G$  is the set of variables occuring globally in it. We define  $elem(a)$  to return a set of elements in  $a$  as

$$elem(a) = \{\dot{t}_1 : \dot{L}_1, \dots, \dot{t}_n : \dot{L}_n\}$$

For an aggregate element of form  $\dot{t}_1 : \dot{L}_1$ , where  $t_1$  is a tuple of terms and  $\dot{L}_1$  is a tuple of comparison literals and atoms

$$dep(\dot{t}_1 : \dot{L}_1) = \{(\emptyset, vars(\dot{t}_1))\} \cup \bigcup_{l \in \dot{L}_1} dep(l)$$

For an aggregate  $a$ , where  $\prec$  is  $=$

$$dep(a) = \{(pt(s), G), (\emptyset, dt(s) \cup G)\}$$

Otherwise

$$dep(a) = \{(\emptyset, G \cup vars(s))\}$$

## 2.4 Rule

For a rule  $r$  in the form of (2) the following holds:

$$dep(r) = \{(\emptyset, vars(H_1 \vee \dots \vee H_k))\} \cup dep(B_1) \cup \dots \cup dep(B_m)$$

## 2.5 Choice Rule

For a choice rule  $r$  in the form of (3) the following holds:

$$dep(r) = \{(\emptyset, vars(e_1 \vee \dots \vee e_k))\} \cup dep(B_1) \cup \dots \cup dep(B_m)$$

## 2.6 Safety Definition

We define operator  $C_r$  for a rule  $r$  applied to a set of variables  $V$  as

$$C_r(V) = \bigcup_{(P,D) \in dep(r), D \subseteq V} P.$$

A rule  $r$  is globally safe if  $vars(r)$  is the least fixed point of  $C_r$  and each aggregate and conditional literal is locally safe.

We define operator  $C_{e,G}$  for an element  $e$  of an aggregate  $a$  applied to a set of variables  $V$  as

$$C_{e,G}(V) = G \cup \bigcup_{(P,D) \in dep(e), D \subseteq V} P.$$

$a$  is locally safe if for each element  $e \in elem(a)$ ,  $vars(e)$  is the least fixed point of  $C_{e,G}$

We define operator  $C_{l,G}$  for an conditional literal  $l$  applied to a set of variables  $V$  as

$$C_{l,G}(V) = G \cup \bigcup_{(P,D) \in dep_l(l), D \subseteq V} P.$$

$l$  is locally safe if  $vars(l)$  is the least fixed point of  $C_{l,G}$

## 3 Other Examples

$$\begin{aligned} dep(p(X, Y + Y)) &= \{(pt(X, Y + Y), \emptyset), (\emptyset, dt(X, Y + Y))\} \\ &= \{(pt(X) \cup pt(Y + Y), \emptyset), (\emptyset, dt(X) \cup dt(Y + Y))\} \\ &= \{(\{X\} \cup \emptyset, \emptyset), (\emptyset, \emptyset \cup vars(Y + Y))\} \\ &= \{(\{X\}, \emptyset), (\emptyset, \{Y\})\} \end{aligned}$$
